FOREWORD

The Defense Logistics Agency (DLA) Directorate of Contracting requested DLA's Operations Research and Economic Analysis Office (DLA-LO) to formulate a management indicator which can provide visibility of the ability of the production base to meet surge and mobilization production needs. To this end, DLA-LO has developed, with the support of DLA's production readiness experts, a prototype indicator which may be used to aid in the selection of items for planning as part of the Industrial Preparedness Program (IPP). This report documents this indicator development effort.

A prototype planning indicator has been developed which is based on the criticality of an item to its application and the uncertainty of availability for an item. Results from a test using the prototype indicator to evaluate the Construction, Electronics, General and Industrial commodities are presented. The prototype indicator shows much promise for identifying items which should be planned to ensure their availability during mobilization.

It is recommended in this study that development of the planning indicator be continued, to provide DLA's Supply Centers with a better methodology for the selection of items for participation in the IPP planning process and provide visibility of the responsiveness of the industrial base to meet emergency demands.

## EXECUTIVE SUMMARY

The Defense Logistics Agency (DLA) performs industrial base mobilization planning as part of its Industrial Preparedness Program (IPP) to increase the likelihood that required materiel resources can be obtained from the industrial base during mobilization. DLA is currently limited to planning only a small percentage of the Services' War Reserve items because of planning resource limitations. Therefore, DLA must focus its planning efforts on those items which are critical to the mobilization effort and which planning can substantially reduce the uncertainty of their availability.

A multi-attribute indicator of the desirability of planning any item has been developed by the DLA Operations Research and Economic Analysis Office with the support of DLA's production readiness experts. The prototype indicator provides an overall relative "goodness" measure by considering six distinct item characteristics: application to the Commanders-in-Chief Critical Items List (CINC CIL) weapons systems, essentiality code, lead time, mobilization demand ratio, age of the item and mobilization demand value. These characteristics were selected because they represent the criticality of an item and its uncertainty of availability.

During the development of the indicator database, we found that there was minimal overlap between the War Reserve requirements submitted by the Services and the items which DLA manages which support the CINC CIL. There may be valid reasons for this disparity, but this issue should be investigated further to ensure that there is no major flaw in our planning process.

The planning indicator has been prototyped for the Construction, Electronics, General, and Industrial commodities to produce a rank-ordered list of candidate items for planning for each Center. Many of these candidate items would be excluded from planning consideration using current item selection criteria because the current approach does not consider that combinations of item characteristics may warrant planning. The prototype planning indicator appears to be a useful tool for aiding in the selection of items for industrial base planning.

We recommend the following:

- o The apparent disparity between CINC CIL supporting items and Service War Reserve Requirements be investigated and resolved.
- o The prototype indicator be modified to address the peculiarities of the Medical and Clothing & Textile commodities.
- o The planning indicator be implemented at DLA's Supply Centers to provide an improved methodology for the selection of items for IPP planning.

## I. INTRODUCTION

A major mission of the Defense Logistics Agency (DLA) is the management of several million consumable items which may be common to two or more of the Military Services. To ensure that items critical to national defense are available during periods of conflict, DLA uses its Industrial Preparedness Program (IPP) planning effort to develop mobilization plans with selected contractors for the production of critical materiel. Each year, the Services submit mobilization requirements for several hundred thousand items as part of their War Reserve program, however, based on limited resources only a small percentage is actually planned with industry. For this reason, it is critical that DLA focus its planning resources on those items with the greatest need.

IPP item planning consists of contractors developing time phased estimates of their mobilization production capabilities for selected items. IPP planning provides visibility of industry's expected mobilization production support and provides advance warning of possible mobilization requirements to selected contractors. This paper describes the process of developing an indicator for IPP item selection and the results from prototype testing.

## II. METHODOLOGY

The DLA Operations Research and Economic Analysis Office has developed for DLA's Directorate of Contracting an indicator for identifying those items for which planning would be of greatest benefit. The indicator is based on a multi-attribute decision making technique known as TOPSIS (Technique for Order Preference by Similarity to Ideal Solution), which was developed by Yoon and Hwang at Kansas State University in 1980. (A similar approach is being utilized by the Joint Chiefs of Staff to prioritize weapon systems.) In this application of the TOPSIS methodology, item characteristics (attributes) have been chosen which represent either the criticality or the availability of an item. Items which are highly critical or have considerable uncertainty about their availability are the most logical candidates for planning given limited planning resources. These items will be further from the ideal combination of item characteristics and will therefore have a lower measure of relative closeness to the ideal solution using TOPSIS.

TOPSIS is a fairly simple technique to evaluate alternatives under a number of distinct criteria (attributes). It is relatively easy to rank various alternatives when desirability is measured in terms of a single characteristic. In general, at one end of the attribute value range is the most desirable value (ideal solution), and at the other end of the value range is the least desirable value (negative-ideal solution). Within this attribute value range, alternatives having attribute values closer to the ideal solution are better, while alternatives having values closer to the negative-ideal solution are worse. When additional characteristics are introduced against which alternative "goodness" is measured the issue becomes more complex. Multi-attribute decision making techniques have been developed for the purpose of ranking alternatives given multiple measurement criteria. TOPSIS is one such multi-attribute technique which allows the evaluation of alternatives when there are multiple attributes to be considered by providing a measure of the relative closeness of an alternative to the most desirable combination of

attributes. The details of this particular application of the TOPSIS methodology are described in the following sections.

### III. ANALYSIS

A. Selection of Ranking Criteria. The motivation for planning items is primarily due to two factors: (1) the importance of particular items, and (2) the uncertainty of availability of items. Therefore, attributes which describe these item characteristics were chosen for inclusion in the planning Indicator. A group of production readiness experts from DLA's Supply Centers was organized to identify these attributes. This group identified twelve attributes as being indicative of item criticality and availability during mobilization. These attributes are:

- o Critical Items List Application      o Age of Item
- o Essentiality Code                    o Demand to Production Lag
- o Lead Time                            o Problem Industry
- o Mobilization Demand Ratio        o Number of Suppliers
- o Size of Shortage                    o Commercial Availability
- o Get Well Date                        o Item Application

B. Indicator Prototyping. As a test of the indicator methodology, the model was to be prototyped using attributes which were readily available in automated databases. Since not all of the attributes chosen by the functional experts were available, only those available in an automated form were used. One additional attribute was introduced to bring the ranking criteria to six in number. The attributes (and their respective weights) selected for the prototyping of the indicator methodology are:

1. CRITICAL ITEMS LIST APPLICATION - (37.5). This was chosen as the most important attribute because of the emphasis on providing support to weapons on the Commanders-in-Chief Critical Items List (CINC CIL). The CINC CIL is a list of weapon systems which the various Commanders-in-Chief have designated as being critical to their war fighting capabilities. This attribute has "yes" and "no" as possible values. An item which has application to a CINC CIL weapon system is given the value "yes".

#### 2. ESSENTIALITY CODE - (34.4)

The essentiality code represents the importance of an item to a weapon system. The valid essentiality codes and their definitions are:

- a. 1 - Failure to this part will render end item inoperable
- b. 3 - Failure to this part will not render end item inoperable

- c. 5- Item does not qualify for code 1 but is needed for personnel safety
- d. 6- Item does not qualify for code 1 but is needed for legal, climatic or other requirements peculiar to the planned operational environment of the end item
- e. 7- Item does not qualify for code 1 but is needed to prevent impairment of or temporary reduction of operational effectiveness of the end item
- f. Blank - Same as code 3 or appropriate service has not assigned an essentiality code

Since an item may have many different essentiality codes based upon particular applications, the highest essentiality code (representing greatest criticality of the item) was used. The ordering of the essentiality codes from highest to lowest criticality in this analysis was [1; 5 & 6 & 7; 3 & Blank]. A possible future enhancement to this methodology might be to compute a weighted essentiality code for each item based upon the magnitude of requirements for each application of the item and their corresponding essentiality codes.

3. LEAD TIME - (12.5). The lead time is the length of time required to produce an item (as represented by the production lead time). This attribute has been chosen because the greater the lead time, the slower the expected response to demands.

4. MOBILIZATION DEMAND RATIO - (9.4). This is the ratio of the mobilization demand requirements to normal peacetime demand. If this ratio is large, the potential for insufficient production base capabilities is greater.

5. AGE OF ITEM - (3.1). This attribute identifies whether the item is new or established. If the item is new to DLA (less than 2 years of management responsibility), there is less certainty of the availability of the item.

6. MOBILIZATION DEMAND VALUE - (3.1). The mobilization demand value is the dollar value of the projected mobilization demand (the Other War Reserve Materiel Requirements). Although this attribute was not among the original twelve selected by the production readiness experts, it was included because it was readily available and a large mobilization demand value could indicate insufficient industrial base capabilities.

#### C. Items Examined

The population of items to be evaluated was developed from two sources. Service War Reserve items, which have been traditionally considered for planning, were merged with items supporting the CINC CIL. Table 1 displays the breakout of items examined by commodity. The development of the indicator database is described in greater detail in Appendix A.

It is interesting to note the general lack of overlap (common items) between the items which DLA manages which support the CINC CIL and the items for which War Reserve requirements are submitted by the Services. Overall, there is less than a ten percent overlap of these two item populations. The discovery of this lack of correlation between the items which the CINC's identify as critical to their mission during mobilization, and the mobilization requirements submitted by the Services as part of the War Reserve program may warrant review of the Services War Reserve computations.

Table 1

INDICATOR DATABASE BREAKDOWN

<u>Commodity</u>	<u>CIL Items</u>	<u>WRMR Items</u>	<u>Unique Items</u>	<u>Common Items</u>
Construction	17,661	29,276	43,772	3,165
Electronic	59,812	43,414	92,794	10,432
General	13,337	17,171	27,348	2,660
Industrial	66,582	67,379	121,781	12,180
Medical	52	11,138	11,164	26
Textile	123	3,047	3,102	68
Total	157,567	171,425	300,461	28,531

D. Indicator Computation

Computation of the indicator value for each item is a relatively simple process. The following briefly describes the indicator computation process:

1. Definition of ideal and negative-ideal values - Rather than specify a "high" or "low" value for these values as typical to a simple TOPSIS application, distinct values were identified for both the ideal and negative-ideal solutions. This was done to limit the influence of items with extreme attribute values. For the prototype indicator effort, the following values were assigned as the ideal and negative-ideal solutions:

	<u>IDEAL</u>	<u>NEG-IDEAL</u>
CIL Application	No	Yes
Essentiality Code	Blank	1
Lead Time	0 days	750 days
Mob Demand Ratio	0	500
Age of Item	Estab.	New
Mob Demand Value	\$ 0	\$ 100,000

2. Assignment of attribute values - Each item was assigned a numeric score for each attribute. Attributes with non-numeric or non-cardinal values were assigned cardinal values. Attribute values for the CIL application, essentiality code and age of item code were assigned as follows:

CIL Application -

No	--->	0.0
Yes	--->	1.0

Essentiality Code -

1	--->	0.0
3	--->	5.5
5	--->	3.5
6	--->	3.5
7	--->	3.5
Blank	--->	5.5

Age of Item Code -

E	--->	1.0
N	--->	2.0
Blank	--->	1.5

3. Clipping of extreme values - Items which had attribute values beyond the bounds of the ideal or negative-ideal values had their values clipped to within these limits.

4. Normalization of attributes - Each of the attributes was normalized to produce an attribute value range of 0 to 1.

5. Application of attribute weights - The normalized attribute vectors were multiplied by the appropriate weighting factors.

6. Computation of distance measures - The Euclidean distances for item state space coordinates to both the ideal and negative-ideal solutions were computed.

7. Computation of indicator value - The relative closeness of each item to the ideal solution was computed by dividing the distance to the negative-ideal by the sum of the distances to the ideal and negative-ideal solutions. This result was subtracted from one to produce an indicator where a higher value (closer to 1.00) represents a greater need for planning.

8. Rank ordering the items - The items were sorted by their indicator value in descending order. This produced a list of candidate items for planning where again, higher indicator scores represented a greater need for industrial base planning.

Appendix B describes the indicator computation process in greater detail and includes listings of the programs developed for indicator value computation. Appendix C provides a step by step example of the indicator computation process for a sample item.

E. Indicator Adjustments. The indicator computation can be fine tuned using various "knobs" inherent to the technique. The two most significant ways to adjust the indicator are (1) through the definition of the ideal and negative-ideal solutions, and (2) by the assignment of the relative attribute weights. During the prototype indicator review process, each of these "knobs" was adjusted to produce results that were in closer agreement with the opinion of DLA's production readiness experts.

#### IV. FINDINGS

It is useful to examine a sample of the prototype indicator's output. Table 2 displays a typical listing of indicator results. The first column labeled "NSN" is the National Stock Number for the item. The second column is labeled "ITEM NAME" and indicates the nomenclature for the item. The third column labeled "PLAN CODE" shows whether the item was planned during the last IPP cycle. A "P" in this column indicates that the item was planned. (Currently this field is only valid for the General commodity.) The fourth column is labeled "INDCTR VALUE" and represents the indicator value which was computed for the item from its attribute values. The list is ordered based on this column, with high values, which indicate a greater need for planning, appearing at the top of the list. The fifth column is labeled "CIL CODE" and has the code "C" if the item is used on a CIL weapon system, and blank otherwise. The sixth column, labeled "ESS CODE", represents the highest essentiality code for any application of that item to a weapon system. The seventh column, "LEAD TIME", is the production lead time for the item. The eighth column, "MOB DMD RATIO", is the mobilization demand ratio for the item. The ninth column, "MOB DEMAND VALUE", is the mobilization demand value for the item expressed in dollars. The tenth and final column is labeled "AGE OF ITEM" and represents the age of item code for the item, where "E" means "established" and "N" means "new". This output listing was designed to display much of the information used for the indicator computation as well as the planning indicator value itself so that the listing might be more useful as a planning tool to production readiness personnel. By displaying this additional information, more informed decisions can be made when selecting items for planning.

The prototype indicator appears to produce results which can be useful in the planning process for DLA's four hardware centers. Results for the top 100 items for each of the hardware centers are presented in Appendices D through G. It appears that the prototype indicator in its present configuration does not address the peculiarities of the items managed by Defense Personnel Support Center (the Medical and Clothing & Textile commodities). An indicator using attributes which are not as weapon system related as those for the hardware centers' indicator would be more appropriate for DPSC.

The approach of a multi-attribute indicator to determine which items should be considered for planning appears to have some advantages over the current method of using independent screening criteria to identify items for planning. The current screening criteria limits planning consideration to items meeting each of the following three criteria:

Table 2

1. Lead time greater than 60 days
2. Other War Reserve Materiel Requirement greater than \$10,000
3. Mobilization demand ratio greater than 3.0

Failure to satisfy one of the criteria removes an item from planning consideration regardless of how the item rates against the other criteria. The new indicator has the advantage that it considers the combination of attribute values to identify candidate items. Weakness in one attribute may be offset by strength in another attribute. Elimination of independent screening criteria will allow the combined effects of the various criteria to be addressed.

The multi-attribute approach also has the advantage of allowing varying degrees of emphasis to be placed on each of the attributes by means of the attribute weighting process. If much greater emphasis on a particular attribute is desired during a given planning cycle, a greater weight can be assigned to that attribute prior to the indicator computation process. The results of the new weight will be reflected in the indicator results.

#### V. CONCLUSIONS

The development of the planning indicator item database has revealed that very little overlap exists between the items for which the Services submit War Reserve requirements and the DLA managed items which support CINC CIL weapons systems. Although these two lists were developed by different groups and for different purposes -- the CINC CIL by the operations planners for ensuring war fighting capabilities, and the War Reserves by the logistics planners for ensuring logistics sustainability -- one would expect a greater overlap in these items than the ten percent that is observed. Possibly, the War Reserve requirements are computed solely on the basis of reliability failures, and do not include any combat damage requirements. Therefore, some disparity between the item populations may exist as some items will not need to be replaced except in the event of combat damage. Nonetheless, the lack of War Reserve requirements for many of the critical items which support the CINC CIL should be reconciled.

This prototyping effort has demonstrated that it is feasible to construct an indicator which is useful in identifying candidate items for industrial base mobilization planning. Ranking items based on item characteristics which indicate item criticality and uncertainty of availability can be a useful method for selecting items for planning. Given the scarcity of production planning resources, planning efforts should focus on those items with the greatest payback from planning -- where the planning will insure the availability of items critical to mobilization efforts. The indicator can also be a useful tool for identifying areas of the industrial base which may warrant further examination. For instance, computing an indicator value across a supply class (averaging the item indicator values for items within a supply class) may reveal potential weaknesses in specific areas of the industrial base. These results might be used to direct studies of weak sectors within the industrial base.

## VI. RECOMMENDATIONS

The following recommendations are made:

- o Investigate the reasons for the disparity between the Services' War Reserve requirements and the CINC CIL supporting items. This can be an opportunity to ensure that the operations planners are communicating with the logistics planners.
- o Develop prototype indicators for the Medical and Clothing & Textile commodities considering the unique characteristics of each of these commodities.
- o Implement the multi-attribute planning indicator methodology as part of the IPP planning process. The methodology should be adapted for use at the Supply Center level. The Directorate of Contracting, DLA Headquarters, should maintain oversight of the application of indicator software at the DLA Supply Centers. (This implementation of the planning indicator may entail developing programs for use on Center mainframe computers (Standard Automated Materiel Management System - SAMMS), minicomputers (Distributed Minicomputer Processing System - DMINS), or microcomputers.)

## APPENDIX A - DATABASE DEVELOPMENT

Development of the indicator databases for each of the different commodities examined was accomplished using the following procedure.

(1) Identification of the CINC CIL related items. The first step in identifying the DLA managed items which are related to the CINC CIL required relating Weapon System Designator Codes (WSDC's) to as many of the CINC CIL systems as possible. After the appropriate WSDC's were identified, a list of DLA managed items for all of the CINC CIL related WSDC's was obtained using information contained in the DIA Integrated Data Base (DIDB).

(2) CINC CIL item data expansion. Additional item information (such as lead time, mobilization demand, etc.) required to compute the indicator values was obtained from differenc files within the DIDB and added to the CINC CIL item database.

(3) Identification of War Reserve items. War Reserve items were identified as those items with an Other War Reserve Materiel Requirement (OWRMR) of greater than zero. In addition to the NSN, much of the data required for indicator computation was pulled at the same time because it was available in the same DIDB files.

(4) War Reserve item data expansion. The essentiality code as obtained from the weapon system file of the DIDB was added to the War Reserve item database.

(5) Merging of the item databases. The CINC CIL item database was merged with the War Reserve item database to produce one combined database. A field indicating the source of each item (CINC CIL, War Reserve, or both) was also added to the data.

(6) Adjustment of essentiality code field. The essentiality code representing the application of highest criticality was used as the essentiality code for each item.

(7) Conversion of data fields to numeric attribute data. Those fields which were either non-numeric or non-cardinal were converted to numeric values. Other indicator attributes which were a combination of item data fields (such as mobilization demand value which is the unit price times the mobilization demand quantity) were also computed.

(8) Addition of planning field. For the General commodity, information was obtained which indicated which items had been planned during the previous planning cycle. This information was appended to the indicator attribute database.

These steps comprise the indicator database development process. The resulting database was used for indicator value computation.

## APPENDIX B - INDICATOR COMPUTATION PROGRAM

### 1. Indicator Computation

A fairly simple FORTRAN 77 program was used to compute the indicator values for each item. This program is composed of the following four modules:

**MAIN** - The main program calls the various subroutines.

**RDSOLN** - This routine reads the attribute names, weights, and the ideal and negative-ideal solutions.

**PROCSS** - This routine computes the normalization factors for each of the attributes.

**COMPUT** - This routine performs the actual computation of the relative closeness to the ideal solution.

### 2. Output Report Generation

The output listings were produced by using the report capabilities of the Statistical Package for the Social Sciences (SPSS). The remaining pages of this appendix represent a listing of the source code of the indicator computation program and the SPSS statements used to produce the output reports.

## APPENDIX C - EXAMPLE OF INDICATOR COMPUTATION

This appendix follows the computation of the planning indicator value for one sample item. The item chosen for this example is managed by the Defense Industrial Supply Center (DISC), specifically NSN 5340001930783 which has the nomenclature "Clamp, Loop". Using our indicator database we determine that this item has the following attribute values:

CIL Application = Yes  
Essentiality Code = 1  
Lead Time = 271 days  
Mob Demand Ratio = 160.0  
Mob Demand Value = \$146,740  
Age of Item = Established

### 1. Assignment of Numeric Attribute Values

The first step in the computation of an indicator value for this item is the assignment of numeric values for each attribute. We use the following attribute value mapping algorithms:

CIL Application -  
    No ---> 0.0  
    Yes ---> 1.0

Essentiality Code -  
    1 ---> 0.0  
    3 ---> 5.5  
    5 ---> 3.5  
    6 ---> 3.5  
    7 ---> 3.5  
    Blank ---> 5.5

Age of Item Code -  
    E ---> 1.0  
    N ---> 2.0  
    Blank ---> 1.5

Using these mapping algorithms, we translate the CIL application, essentiality code, and age of item attributes to the following numeric values:

CIL Application = 1.0  
Essentiality Code = 0.0  
Age of Item = 1.0

## 2. Clip Extreme Attribute Values

The next step is to clip any attribute values which lie outside of the ideal and negative-ideal solutions. This places the following constraints on the attribute values:

```
0.0 <- CIL Application <- 1.0  
0.0 <- Essentiality Code <- 5.5  
0 <- Lead Time <- 750  
0.0 <- Mob Demand Ratio <- 500.0  
0 <- Mob Demand Value <- 100,000  
1.0 <- Age of Item <- 2.0
```

The only attribute which must be clipped in this example is the mobilization demand value attribute since \$146,740 is greater than the \$100,000 maximum allowed value. This produces the attribute value set of:

```
CIL Application = 1.0  
Essentiality Code = 0.0  
Lead Time = 271  
Mob Demand Ratio = 166.0  
Mob Demand Value = 100,000  
Age of Item = 1.0
```

## 3. Normalization

The next step requires normalizing each attribute. Normalization makes the highest value of one attribute equivalent (numerically) to the highest value of another attribute. For our normalization, we are mapping the values for each attribute into the range from zero to one. Each attribute is normalized by subtracting any displacement of the minimum value from zero from the attribute value and dividing the value by the range of values (maximum minus minimum). This normalization can be expressed as

$$\text{NORMALIZED VALUE} = (\text{OLD VALUE} - \text{MINIMUM}) / (\text{MAXIMUM} - \text{MINIMUM})$$

The following computations are performed to normalize our sample item

```
CIL Application = (1.0 - 0.0) / (1.0 - 0.0) = 1.0  
Essentiality Code = (0.0 - 0.0) / (5.5 - 0.0) = 0.0
```

Lead Time = ( 271 - 0 ) / ( 750 - 0 ) = 0.361

Mob Demand Ratio = ( 166.0 - 0.0 ) / ( 500.0 - 0.0 ) = 0.322

Mob Demand Value = ( 100000 - 0 ) / ( 100000 - 0 ) = 1.0

Age of Item = ( 1.0 - 1.0 ) / ( 2.0 - 1.0 ) = 0.0

#### 4. Application of Attribute Weights

Next, we multiply the normalized attribute values by their respective attribute weights. The weighting process can be expressed by

WEIGHTED VALUE = NORMALIZED VALUE \* WEIGHT

Applying the appropriate attribute weights yields

CIL Application = 1.0 \* 37.5 = 37.5

Essentiality Code = 0.0 \* 34.4 = 0.0

Lead Time = 0.361 \* 12.5 = 4.51

Mob Demand Ratio = 0.332 \* 9.4 = 3.12

Mob Demand Value = 1.0 \* 3.1 = 3.1

Age of Item = 0.0 \* 3.1 = 0.0

#### 5. Compute Distances to Ideal and Negative-Ideal Solutions

After the weighted normalized attribute values have been computed, the Euclidean distances to the ideal and negative-ideal solutions must be computed. The general algorithm to compute the Euclidean distance between two points is

DISTANCE = ( ( X1 - X2 )^2 + ( Y1 - Y2 )^2 + . . . )^0.5

where X and Y represent two of the dimensions (attributes) which define the coordinate system. First, we apply this algorithm to compute the distance to the ideal solution.

Dist(ideal) = ( ( 0.0 - 37.5 ) ^ 2 +  
                  ( 34.4 - 0.0 ) ^ 2 +  
                  ( 0.0 - 4.51 ) ^ 2 +  
                  ( 0.0 - 3.12 ) ^ 2 +  
                  ( 0.0 - 3.10 ) ^ 2 +  
                  ( 0.0 - 0.0 ) ^ 2 ) ^ 0.5 = 51.3

The distance to the negative-ideal solution is computed

$$\begin{aligned} \text{Dist(neg-ideal)} = & ( ( 37.5 - 37.5 ) ^ 2 + \\ & ( 0.0 - 0.0 ) ^ 2 + \\ & ( 12.5 - 4.51 ) ^ 2 + \\ & ( 9.4 - 3.12 ) ^ 2 + \\ & ( 3.1 - 3.10 ) ^ 2 + \\ & ( 3.1 - 0.0 ) ^ 2 ) ^ {0.5} = 10.6 \end{aligned}$$

#### 6. Indicator Computation

Finally, the indicator which expresses the relative closeness of the item to the ideal solution is computed by the formula

$$\text{INDICATOR} = 1.0 - (\text{Dist(neg-ideal)} / (\text{Dist(neg-ideal)} + \text{Dist(ideal)}))$$

This makes our final computation

$$\text{INDICATOR} = 1.0 - (10.6 / (10.6 + 51.3)) = 0.828$$
